

ASSIGNMENT-3.1

Name : P.Resmitha Reddy

Rollno :2403A510A7

Batch : 05

Course : AI Assisted Coding

Task:

Lab Experiment: Prompt Engineering – Improving Prompts and Context Management (0.5 marks)

Objective

Week2 -

Monday

To explore how prompt design and context influence AI-generated outputs and to learn techniques to improve AI responses.

Tools Required

- GitHub Copilot / Google Gemini / ChatGPT
- VS Code / Google Colab
- Internet access

Procedure

1. Select a simple task: "Write a Python function to check if a number is prime."
2. Use different prompting strategies to generate the solution:
 - a) Zero-Shot – no examples.
 - b) One-Shot – one example provided.
 - c) Few-Shot – multiple examples provided.
 - d) Context-Managed – detailed prompt with constraints and instructions.
3. Record AI responses and refine prompts to improve code

quality.

4. Request AI to optimize the logic for efficiency.

5. Compare results and document improvements.

1. Sample Prompts

- Zero-Shot:

Write a Python function to check if a number is prime.

- One-Shot:

Example: Input: 5 → Output: Prime. Now, write a function to check if a number is prime.

- Few-Shot:

Example 1: Input: 7 → Output: Prime

Example 2: Input: 10 → Output: Not Prime

Example 3: Input: 2 → Output: Prime
Generate the function accordingly.

- Context-Managed (With Optimization)

1. Zero-Shot Prompt

Prompt:

Write a Python function to check if a number is prime.

AI Response:

python

```
def is_prime(n):  
    if n <= 1:  
        return False  
    for i in range(2, n):  
        if n % i == 0:  
            return False  
    return True
```

2. One-Shot Prompt

Prompt:

Example: Input: 5 → Output: Prime. Now, write a function to check if a number is prime.

AI Response:

python

```
def is_prime(n):  
    if n <= 1:  
        return "Not Prime"  
    for i in range(2, n):  
        if n % i == 0:  
            return "Not Prime"  
    return "Prime"
```

3. Few-Shot Prompt

Prompt:

Example 1: Input: 7 → Output: Prime
Example 2: Input: 10 → Output: Not Prime
Example 3: Input: 2 → Output: Prime
Generate the function accordingly.

AI Response:

python

```
def is_prime(n):  
    if n <= 1:  
        return "Not Prime"  
    for i in range(2, int(n**0.5) + 1):  
        if n % i == 0:  
            return "Not Prime"
```

4. Context-Managed Prompt (With Optimization)

Prompt:

Write an efficient Python function to check if a number is prime.

- "Return "Prime" or "Not Prime"."
- "Optimize by checking divisibility only up to the square root of the number."
- "Handle edge cases for numbers less than or equal to 1."
- "Code should be concise and readable."

AI Response:

python

```
def is_prime(n):
    if n <= 1:
        return "Not Prime"
    if n <= 3:
        return "Prime"
    if n % 2 == 0 or n % 3 == 0:
        return "Not Prime"
    i = 5
    while i * i <= n:
```

AI Response:

python

```
def is_prime(n):
    if n <= 1:
        return "Not Prime"
    if n <= 3:
        return "Prime"
    if n % 2 == 0 or n % 3 == 0:
        return "Not Prime"
    i = 5
    while i * i <= n:
        if n % i == 0 or n % (i + 2) == 0:
            return "Not Prime"
        i += 6
    return "Prime"
```

5. Comparison & Observations

- **Zero-Shot:** Basic, works but inefficient (checks all numbers up to n).
- **One-Shot:** Similar to Zero-Shot but introduces output format.
- **Few-Shot:** Better logic (uses square root check).
- **Context-Managed:** Most efficient ($6k \pm 1$ rule, fewer checks).

6. Documentation of Improvements

- Moved from brute-force to optimized algorithms.
- Added constraints for readability and performance.
- Prompt refinement directly improved logic quality.

Task:

Use Python programming and AI-assisted coding tools to create an application that simulates mobile data billing for a telecom service provider.

Instructions

1. Use GitHub Copilot or Google Gemini to assist in writing the program.

2. Read the following inputs from the user:

- o Data Consumed (in GB)
- o Plan Type (Prepaid / Postpaid)
- o Additional Services Used (e.g., caller tune, OTT subscription, etc.)

3. Implement billing logic to calculate:

- o DC (Data Charges) – charges based on data consumption
- o VC (Value-added Charges) – charges for additional services
- o Tax – applicable tax on the total bill

4. Display an itemized bill showing:

- o Plan Type
- o Data Usage and Charges
- o Value-added Services and Charges
- o Tax
- o Total Bill Amount

Requirements

- Students must refer to their actual mobile bill for charge structure (data cost, service fees, taxes) to make the program

Week2 -

Monday

realistic.

- AI assistance (Copilot/Gemini) must be used to generate and refine the initial code.

Deliverables

- AI prompts used for code generation.
- AI-generated Python code and any optimized version.
- Screenshots of:
 - o AI interactions
 - o Program execution and output
 - o Comparison with the student's actual mobile bill

```
# A dictionary to store pricing for various services

    main()

```

Comparison with an Actual Mobile Bill

The implemented program's logic closely mirrors key aspects of an actual mobile bill from a major Indian telecom provider.

- **Plan Type and Charges:** The simulation distinguishes between **Prepaid** and **Postpaid** plans, which is a fundamental division in the telecom industry. The tiered pricing for postpaid is a common practice to encourage higher usage.
- **Itemized Billing:** The program breaks down the bill into logical sections: **Data Charges**, **Value-added Charges**, **Tax**, and **Total Amount**. This itemization is standard on all official bills, providing transparency.
- **Tax Calculation:** The program applies a fixed tax rate (18% GST), which is a crucial component of mobile billing in many regions, including India.
- **Value-added Services:** The inclusion of charges for services like `caller tune` and `OTT subscription` makes the simulation more realistic, as these are common additions to standard mobile plans.

Scenario 1: Prepaid Plan with a single service

```
Welcome to the Mobile Data Billing Simulator!
Enter data consumed (in GB): 8
Enter plan type (Prepaid / Postpaid): prepaid
Enter additional services (e.g., caller tune, ott subscription) or leave blank: caller tune

Data Charges (Prepaid): ₹80.00 (₹10/GB)

Value-Added Services:
- Caller Tune: ₹50.00

=====
ITEMIZED BILL
=====
Plan Type: Prepaid
-----
Data Usage: 8.00 GB
Data Charges (DC): ₹80.00
Value-added Charges (VC): ₹50.00
-----
Subtotal: ₹130.00
Tax (18.0%): ₹23.40
=====
Total Bill Amount: ₹153.40
=====
```

Scenario 2: Postpaid Plan with multiple services

```
Welcome to the Mobile Data Billing Simulator!
Enter data consumed (in GB): 12.5
Enter plan type (Prepaid / Postpaid): postpaid
Enter additional services (e.g., caller tune, ott subscription) or leave blank: ott

Data Charges (Postpaid): ₹105.00 (₹15 for first 5GB, ₹2/GB thereafter)

Value-Added Services:
- Ott Subscription: ₹150.00
- Insurance: ₹80.00

=====
ITEMIZED BILL
=====
Plan Type: Postpaid
=====
Data Usage: 12.50 GB
Data Charges (DC): ₹105.00
Value-added Charges (VC): ₹230.00
=====
Subtotal: ₹335.00
Tax (18.0%): ₹60.30
=====
Total Bill Amount: ₹395.30
=====
```

Task:

Apply your Python programming skills and utilize AI-assisted coding tools to build an application that calculates the LPG bill based on specified customer inputs and billing parameters.

Instructions

1. Use GitHub Copilot or Google Gemini to assist in writing and refining the program.
2. Read the following user inputs:
 - o Cylinder Type (Domestic 14.2 kg / Domestic 5 kg / Commercial 19 kg / Commercial 47.5 kg)
 - o Number of Cylinders Booked
 - o Subsidy Amount (applicable only for domestic cylinders)
3. Refer to the given LPG Price List to determine the price per cylinder:
 - o Domestic LPG (14.2 kg) → ₹905.00

- o Domestic LPG (5 kg) → ₹335.50
- o Commercial LPG (19 kg) → ₹1,886.50
- o Commercial LPG (47.5 kg) → ₹4,712.00

Week2 -

Monday

- o Delivery Charges (₹10 to ₹50)

4. Implement the billing formula:

Bill Amount = (Price per Cylinder × Quantity) - Subsidy (if applicable) + Delivery Charges

5. Calculate and display an itemized bill including:

- Cylinder Type
- Number of Cylinders
- Base Amount
- Subsidy
- Delivery Charges
- Total Bill Amount

Deliverables

- A report containing:
 - o AI prompts used to generate the program
 - o AI-generated Python code
 - o Line-by-line explanation of the code

```

1 import random
2
3 # AI Prompt: Create a Python dictionary named 'CYLINDER_PRICES' that stores the prices for different LPG cylinder types
4 # based on the given price list: Domestic 14.2 kg (₹905.00), Domestic 5 kg (₹335.50), Commercial 19 kg (₹1,886.50), and
5 # Commercial 47.5 kg (₹4,712.00).
6 CYLINDER_PRICES = {

    except ValueError:
        print("Invalid input. Please enter a valid number for the number of cylinders or subsidy amount.")

if __name__ == "__main__":
    main()

```

Explanation:

The program is structured into three main parts: a data dictionary, a calculation function, and

a main function for user interaction. **import random:** This line imports the random module from Python's standard library.

The program uses this module to generate a random number for the delivery charge, which simulates a variable cost.

CYLINDER_PRICES: This is a dictionary that acts as a lookup table for the prices of different LPG cylinders. Using a dictionary makes the code organized and easy to

read. Each key in the dictionary is the name of a cylinder type (like 'domestic 14.2 kg'), and its corresponding value is the price.

□ **calculate_bill() function:** This is the core logic of the program.

- It takes three arguments: the cylinder_type, the num_cylinders booked, and the subsidy_amount.

- It uses CYLINDER_PRICES.get(cylinder_type) to safely retrieve the price of the specified cylinder. If the cylinder type doesn't exist in the dictionary, .get()

returns None, which is then checked to prevent an error.

- The base_amount is calculated by multiplying the cylinder's price by the number of cylinders.

- random.uniform(10.0, 50.0) generates a random floating-point number

between 10.0 and 50.0 to represent the delivery_charges.

- The total_bill is calculated using the formula you provided: (base_amount - subsidy_amount) + delivery_charges.

- Finally, the function returns a dictionary containing all the calculated values (base_amount, subsidy, delivery_charges, and total_bill), which makes it easy to access these values later.

□ **main() function:** This is the entry point where the program starts.

- It begins with a welcome message and lists the available cylinder types to

guide the user.

- The while True loop creates a cycle that keeps prompting the user for input until all inputs are valid.
- It uses input() to get user data for the cylinder type, number of cylinders, and subsidy. The .strip().lower() methods are used to clean the user's input, making it case-insensitive and removing any leading/trailing spaces.
- The code includes input validation. It first checks if the entered cylinder_type is a valid key in the CYLINDER_PRICES dictionary. If not, it prints an error and the loop continues.
- A try-except block is used to catch a ValueError if the user enters text instead of a number for the number of cylinders or the subsidy amount.
- A special check is made for domestic cylinders to determine if a subsidy is applicable.
- Once valid input is received, the calculate_bill() function is called, and the returned dictionary is stored.
- The program then prints a neatly formatted, itemized bill using f-strings to display all the details, including the base amount, subsidy, delivery charges, and total.
- Finally, break is used to exit the loop once a successful bill has been

calculated.

□ **if `__name__` == `"__main__"`:** This is a standard Python convention. It ensures that the `main()` function is called only when the script is executed directly (not when it is imported as a module into another script).
